Part I

Mathematical Analysis

Chapter 1

Metric Space and Continuous Mapping

§1 Metric Space

Definition 1.1 (Metric). A function

$$d: X^2 \rightarrow \mathbb{R}$$

$\forall x, y, z \in X$ satisfying:

- a) $d(x, y) = 0 \leftrightarrow x = y$;
- b) $d(x, y) = d(y, x)$ (symmetry);
- c) $d(x, z) \leq d(x, y) + d(y, z)$ (triangle inequality),

is called a **metric** or **distance** in X . Such X is said to be equipped with a metric d , (X, d) is called a **metric space**. If the metric defined over X is definite, we just simply call the X the metric space.

Some examples:

- We can define $\mathbb{R}_p^n := (\mathbb{R}^n, d_p)$, where

$$d_p(x, y) := \left(\sum_{i \in n} |x^i - y^i|^p \right)^{1/p}, \quad (1-1)$$

while

$$d_\infty(x, y) := \max_{i \in n} |x^i - y^i|. \quad (1-2)$$

- Similarly we can define metric spaces as $(C[a, b], d_p)$ or simplified $C_p[a, b]$.

$$d_p(f, g) = \left(\int_a^b |f - g|^p dx \right)^{1/p}. \quad (1-3)$$

while $C_\infty[a, b]$ is called a **Chebyshev metric**, where the metric is defined as $d_\infty(f, g) := \max_{x \in [a, b]} |f(x) - g(x)|$.

- On equivalence class $\tilde{\mathfrak{R}}[a, b]$ over $\mathfrak{R}[a, b]$ similar metric can be defined. Functions are considered equivalent if they are equal up to a null set.

Lemma 1 (Quadruple inequality). *Let (X, d) be a metric space.*

$$\forall a, b, u, v \in X, |d(a, b) - d(u, v)| \leq d(a, u) + d(b, v) \quad (1-4)$$

Proof. Without loss of generality, we assume that $d(a, b) > d(u, v)$. According to the triangle inequality (see def. 1.1), $d(a, b) \leq d(a, u) + d(u, v) + d(v, b)$, which is to prove. \square

Definition 1.2 (δ -ball). Let (X, d) be a metric space, and $\delta \in \mathbb{R}_+$, $a \in X$. A set

$$B(a; \delta) = \{x \in X \mid d(a, x) < \delta\}$$

is then called a **ball** with a centre at $a \in X$ and a radius of δ , or a **ball** of point a .

Definition 1.3 (Open set). An **open set** $G \in 2^X$ in a metric space (X, d) is a set that satisfies: $\forall x \in G, \exists \delta \in \mathbb{R}_+$, s.t. $B(x, \delta) \subset G$.

Definition 1.4 (Closed set). A **closed set** $F \in 2^X$ in a metric space (X, d) is a set that satisfies: $X - F$ is an open set in (X, d) .

A **closed ball** $\bar{B}(X, \delta) := \{x \in X \mid d(a, x) \leq r\}$ is an example of closed sets in (X, d) .

Proposition 1. a) An infinite union of open sets is an open set.

b) A definite intersection of open sets is an open set.

c) A definite union of closed sets is a closed set.

d) An infinite intersection of closed sets is a closed set.

Proof. Let $\forall \alpha \in A$, G_α be open sets.

a) $\forall x \in \bigcup_{\alpha \in A} G_\alpha, \exists \alpha \in A$ s.t. $x \in G_\alpha$. Since G_α is open, $\exists \delta \in \mathbb{R}_+$ s.t. $B(x, \delta) \subset G_\alpha \subset \bigcup_{\alpha \in A} G_\alpha$.

b) Let G_1, G_2 be open sets in (X, d) . $\forall a \in G_1 \cap G_2, \exists \delta_1, \delta_2 \in \mathbb{R}_+$ s.t. $B(a; \delta_1) \subset G_1, B(a; \delta_2) \subset G_2$. Without loss of generality, let $\delta_1 \geq \delta_2$, therefore $a \in B(a; \delta_1) \cap B(a; \delta_2) = B(a; \delta_2) \subset G_1 \cap G_2$.

c) Just consider $\mathbb{C}_X(\bigcap_{\alpha \in A} F_\alpha) = \bigcup_{\alpha \in A} \mathbb{C}_X(F_\alpha)$ and a).

d) Similarly, $\mathbb{C}_X(F_1 \cup F_2) = \mathbb{C}_X(F_1) \cap \mathbb{C}_X(F_2)$.

\square

Definition 1.5 (Neighbourhood). If $x \in X$ is an element of an open set, then such open set is called a **neighbourhood** of point x in X , denoted by $U(x)$. The collection of all neighbourhoods of x can be denoted by $\mathcal{U}(x)$.

Definition 1.6 (Interior point). Let $x \in X, E \subset X$.

a) If $\exists U(x) \subset E$, x is called an **interior point** of E .

b) If $\exists U(x) \subset X - E$, x is called an **exterior point** of E .

c) If x isn't an interior point nor exterior point of E , it is called a **boundary point** of E . The set of boundary points is called **boundary**, denoted by ∂E .

Definition 1.7 (Limit point). $a \in X$, $E \subset X$. If $\forall U(a)$, $\text{card}(E \cap U(a)) = \infty$, a is called a **limit point** of E .

Definition 1.8 (Closure). The intersections of $E \subset X$ and set of all its limit points is called the **closure** of E , denoted by \overline{E} .

Theorem 1.1. Let $F \in 2^X$. F is a closed set in $X \leftrightarrow \overline{F} = F$.

Proof. \rightarrow : $\mathcal{C}_X(F)$ is open, hence its elements are all its interior points. Therefore $\overline{F} - F = \overline{F} \cup \mathcal{C}_X(F) = \emptyset$, also we know that $F \subset \overline{F}$, hence $F = \overline{F}$.

\leftarrow : $F = \overline{F}$ means that $\forall x \in \mathcal{C}_X(F)$, x is not a boundary of F , which implies that x is an interior point of $X - F$. Therefore $X - F$ is open while F is closed. \square

Theorem 1.2. \overline{E} is always closed.

Proof. $\forall x \in X - \overline{E}$, since it is not an element of the set E nor its limit points, $\exists U(x)$ s.t. $U(x) \cap \overline{E} = \emptyset$, which implies that x is an exterior point of E , therefore \overline{E} is closed. \square

Theorem 1.3. $\overline{\overline{E}} = \overline{E}$.

Proof. Since \overline{E} is closed, its complement is open, which implies that its elements are all exterior points of \overline{E} , therefore \overline{E} has contained all of its limit points. \square

Definition 1.9. (Metric subspace) We called $(X'; d')$ a **subspace** of (X, d) when $X' \subset X$ and $\forall x, y \in X'$, $d'(x, y) = d(x, y)$.

§2 Topological Space

Definition 2.1 (Topology). We say X is equipped with a **topology** if we assigned a $\mathcal{T} \subset 2^X$, with the following properties:

- a) $\emptyset \in \mathcal{T}$; $X \in \mathcal{T}$.
- b) $(\forall \alpha \in A, G_\alpha \in \mathcal{T}) \rightarrow \bigcup_{\alpha \in A} G_\alpha \in \mathcal{T}$.
- c) $\forall G_1, G_2 \in \mathcal{T}$, $G_1 \cap G_2 \in \mathcal{T}$.

We call (X, \mathcal{T}) a **topological space**, and sometimes we might simply call X the topological space.

These conditions are the intrinsic properties of the open sets we have defined in the metric space¹. The topology consisting of all the open sets defined in the metric space $(\mathbb{R}; d_2)$ is called the **standard topology** of the n -dimension Euclidean space.

Definition 2.2 (Open set). Topology \mathcal{T} 's elements are called **open sets**, and their complements are called **closed sets**.

Definition 2.3 (Base). Let (X, \mathcal{T}) be a topological space, and $\mathfrak{B} \subset 2^X$. If $\forall G \in \mathcal{T}$, $\exists \{B_\alpha\}_{\alpha \in A} \in 2^{\mathfrak{B}}$ s.t. $\bigcup_{\alpha \in A} B_\alpha = G$, we called \mathfrak{B} a (topological or open) **base** of the topology \mathcal{T} .

Definition 2.4 (Weight). The smallest possible cardinality of a base of a topology is called the **weight** of the topological space.

¹See proposition 1

Definition 2.5 (Neighbourhood). If $x \in U(x)$ and $U(x) \in \mathcal{T}$, then $U(x)$ is a **neighbourhood** of x in topological space (X, \mathcal{T}) . All neighbourhoods of a point x is denoted by $\mathcal{U}(x)$.

If $\dot{U}(x) := U(x) - \{x\} \neq \emptyset$, then it is a **deleted neighbourhood**. The collection of deleted neighbourhoods of x is denoted as $\dot{\mathcal{U}}(x)$.

For example, we define an equivalence relation \sim in $C(\mathbb{R}; \mathbb{R})$. If $f, g \in C(\mathbb{R}; \mathbb{R})$, at point $a \in \mathbb{R}$:

$$f \sim_a g \leftrightarrow \exists U(a) (\forall x \in U(a), f(x) = g(x)). \quad (2-1)$$

By collecting all of the continuous functions that are equivalent to f , we call f define a **germ** at point a , denoted by f_a . If $f \in C(\mathbb{R}; \mathbb{R})$ is defined in $U(a)$, then we can call $\{f_x \mid x \in U(a)\}$ a neighbourhood of germ f_a . Class of neighbourhoods of each f_x constructs a base of topological space $(C(\mathbb{R}; \mathbb{R}); \mathcal{T})$, where \mathcal{T} is made of the sets of germs of continuous function in $C(\mathbb{R}; \mathbb{R})$.

Definition 2.6 (Hausdorff space). We call a topological space (X, \mathcal{T}) a **Hausdorff space**, **separated space** or T_2 **space**, if $\forall x, y \in X, x \neq y \rightarrow (\exists U(x), U(y) \text{ s.t. } U(x) \cap U(y) = \emptyset)$ ².

Definition 2.7 (Dense set). $E \subset X$ is a **dense set** in the topological space (X, \mathcal{T}) , if $\forall x \in X, \forall U(x), U(x) \cap E \neq \emptyset$.

Definition 2.8 (Separable). If there is a **countable** dense set in topological space (X, \mathcal{T}) , then (X, \mathcal{T}) is **separable**.

We can also define interior points, exterior points, boundary points, limit points in topological space as in metric space.

Definition 2.9 (Topological subspace). Each subset Y of X equipped with topology \mathcal{T} can be given a **subspace topology** \mathcal{T}_Y whose elements G_Y are intersections of the subset with an open set G in (X, \mathcal{T}) i.e. $\forall G_Y \in \mathcal{T}_Y, \exists G \in \mathcal{T} \text{ s.t. } G_Y = G \cap Y$. Subsets equipped with such topology construct a **topological subspace** (Y, \mathcal{T}_Y) .

If two topology $\mathcal{T}_1, \mathcal{T}_2$ are defined on the same X , \mathcal{T}_1 is said to be **stronger** than \mathcal{T}_2 if $\mathcal{T}_1 \subsetneq \mathcal{T}_2$.

Definition 2.10 (Direct product). Let (X_1, \mathcal{T}_1) and (X_2, \mathcal{T}_2) be two topological spaces. Their **direct product** is defined as $(X_1 \times X_2, \mathcal{T})$, where \mathcal{T} has a basis $\mathcal{B} := \{G_1 \times G_2 \mid G_1 \in \mathcal{T}_1 \wedge G_2 \in \mathcal{T}_2\}$.

§3 Compact Set

Definition 3.1 (Open cover). Let (X, \mathcal{T}) be a topological space, $K \in 2^X$ and $\Omega \in 2^{\mathcal{T}}$. We call Ω to be an **open cover** over K , if $K \subset \cup \Omega$. If there are two open covers Ω, Ω' over K , and $\Omega' \subset \Omega$, we say that Ω' is a **subcover** of Ω .

Definition 3.2 (Compact set). A set $K \in 2^X$ in topological space (X, \mathcal{T}) is called a **compact set** if each of its open covers has a **finite** subcover.

Specially, \emptyset is compact.

Theorem 3.1. A set $K \subset X$ is compact in (X, \mathcal{T}) iff K is compact in (K, \mathcal{T}_K) itself.

²This definition is also called **Hausdorff axiom** or **separation axiom**.

This theorem tells a truth that whether K is compact or not doesn't depend on the topological space it's in. This fact can be easily proved: we just need to notice that every open set G_K in (K, \mathcal{T}_K) is an intersection of an open set G in (X, \mathcal{T}) and K .

Theorem 3.2 (Compact \rightarrow closed (Hausdorff)). *If K is compact in a Hausdorff space (X, \mathcal{T}) ³, then K is a closed set in (X, \mathcal{T}) .*

Proof. Let x_0 be a limit point of K , which means $\forall U(x_0)$,

$$\text{card } U(x_0) \cap K \notin \mathbb{N}.$$

Assume that $x_0 \notin K$. In a Hausdorff space, $\forall x \in K - \{x_0\}$, $\exists U(x)$ s.t. $U(x) \cap U(x_0) = \emptyset$. Such $U(x)$ construct an open cover $\Omega = \{U(x) | x \in K\} \subset 2^K$. Since K is compact, $\exists \Omega' \subset \Omega$ s.t. $\text{card } \Omega' \in \mathbb{N}$.

$$(\cup \Omega') \cap U(x_0) = \left(\bigcup_{k=1}^n U_k \right) \cap U(x_0) = \bigcup_{k=1}^n (U_k \cap U(x_0)) = \emptyset.$$

Since $K \subset \cup \Omega'$, x_0 is an exterior point of K , which leads to a contradiction.

Hence $x_0 \in K$. $\bar{K} = K$. □

Theorem 3.3. *Each decreasing nested sequences of non-empty compact sets has a non-empty limit, i.e. $\forall (K_n)_{n \in \mathbb{N}} \in \mathcal{P}(X)^{\mathbb{N}}$ s.t. $\forall n \in \mathbb{N}_+$, $K_n \supset K_{n+1} \wedge K_n \neq \emptyset \wedge (K_n \text{ is compact}): K_n \downarrow K \neq \emptyset$.*

Proof. Assume that $K = \emptyset$. Compact subsets of K_1 are all closed, while their complements are all open. An open cover Ω can be constructed as $\{K_1 - K_n \mid n \in \mathbb{N}_+\}$. Since K_1 is compact, there would be a finite subcover $\Omega' \subset \Omega$, notice that $(X - K_n)_{n \in \mathbb{N}}$ is also a nested sequence, there must be one single $X - K_{n_0} \in \Omega'$ that covers K_1 , which means $K_{n_0} = \emptyset$ contradicting that $\forall n \in \mathbb{N}_+$, K_n is non-empty. □

Theorem 3.4. *A Closed subset F of a compact set K is also compact.*

Proof. If $\Omega_F \subset 2^K$ is an open cover of F . Notice that $K - F$ is open, $\Omega = (\cup \Omega_F) \cap \{K - F\}$ constructs an open cover over K . Since K is compact there must be a finite cover $\Omega' \subset \Omega$ which obviously also covers over F . □

The following properties of compact sets are about topological spaces induced from metric spaces.

Definition 3.3 (net). (X, d) is a metric space, $E \in 2^X$. E is called an ε -**net** if $\forall x \in X, \exists e \in E$, $d(e, x) < \varepsilon$.

Theorem 3.5 (Finite ε -net exists). *If (K, d) is a compact metric space, then $\forall \varepsilon \in \mathbb{R}_+$, \exists finite ε -net in (K, d) .*

Proof. For each point $x \in K$, find it a $B(x, \varepsilon)$, of which an infinite cover Ω over K is made. Since K is compact, there exists a finite subcover $\Omega' = \{B(x_i, \varepsilon)\}_{i \in n}$ ($n \in \mathbb{N}_+$). Therefore $\{x_i\}_{i \in n}$ is a finite ε -net in K . □

³See definition 2.6.

Theorem 3.6 (Sequentially compact). *A metric space (K, d) is compact iff it is sequentially compact, that is, $\forall (x_n)_{n \in \mathbb{N}} \in K^{\mathbb{N}}$, it has a convergent subsequence $(x_{k_n})_{n \in \mathbb{N}}$ ($k_n \in \mathbb{N}$; $k_{n+1} > k_n$) whose limit $a \in K$.*

To prove Theorem 3.6, we need to prove two lemmata first.

Lemma 2. *If (K, d) is sequentially compact, then $\forall \varepsilon \in \mathbb{R}_+$, \exists finite ε -net in (K, d) .*

Proof. Assume that $\exists \varepsilon_0 \in \mathbb{R}_+$, there were no finite ε_0 -net in (K, d) . Define such sequence: $(x_n)_{n \in \mathbb{N}}$ s.t. $\forall n \in \mathbb{N} \forall k \in n$, $d(x_n, x_k) \geq \varepsilon_0$ (There would always be a next one since there exists no finite ε_0 -net or $\{B(x_n; \varepsilon_0)\}_{n \in \mathbb{N}}$ gives such). It has no convergent subsequence: if there were a $(x_{k_n})_{n \in \mathbb{N}}$ convergent to $a \in K$, $\exists N, M \in \mathbb{N}_+$, $d(x_N, x_M) \leq d(x_N, a) + d(x_M, a) \leq \varepsilon_0$, which lead to a contradictory. \square

Lemma 3. *If (K, d) is sequentially compact then every nested sequence of closed non-empty sets $\{F_n\}_{n \in \mathbb{N}}$ in K have a non-empty intersection.*

Proof. Let $(x_{k_n})_{n \in \mathbb{N}}$ be a convergent subsequence of $(x_n)_{n \in \mathbb{N}}$, where $\forall n \in \mathbb{N}$, $x_n \in F_n$. Let a be the limit of $(x_{k_n})_{n \in \mathbb{N}}$.

Assume that $a \notin \bigcap_{n \in \mathbb{N}} F_n$, in a metric space, $\exists U(a) \in \mathcal{U}(a)$ s.t. $U(a) \cap (\bigcap_{n \in \mathbb{N}} F_n) = \emptyset$, therefore $U(a) \cap (\bigcap_{n \in \mathbb{N}} F_{k_n}) = \emptyset$. But this conflict the fact that $\exists N \in \mathbb{N}$, s.t. $n > N \rightarrow x_{k_n} \in U(a)$ while $x_{k_n} \in F_{k_n}$. \square

Then we get back to the Theorem 3.6.

Proof. \rightarrow : If $\text{card}\{x_n\}_{n \in \mathbb{N}} \in \mathbb{N}$, it is obvious; Now we let $\text{card}\{x_n\}_{n \in \mathbb{N}} \notin \mathbb{N}$. We can always find finite $1/k$ -net $\{B(a_{k,i}, 1/k)\}_{i \in m}$ (Theorem 3.5, $m \in \mathbb{N}$, $a_i \in K$), for all $k \in \mathbb{N}_+$. For each k , there must be at least one $B(a_{k,i_0}, 1/k)$ (for simplification, we denote a_{k,i_0} by a_k) that includes infinite elements in $(x_n)_{n \in \mathbb{N}}$. $\forall n \in \mathbb{N}_+$ (let $k_0 = 0$), select $x_{k_n} \in B(a_{n,0}, 1/n)$, and $\{\overline{B}(x_n; 1/k)\}$ is a nested sequence of a closed non-empty sets in sequentially compact K , (Lemma 3) $\lim_{n \rightarrow \infty} x_{k_n} \in K$.

\leftarrow : Assume that there were an open cover Ω over K having no finite subcover, $\forall n \in \mathbb{N}_+$, \exists finite $1/n$ -net (Lemma 3), in which there would be at least one x_n whose $\overline{B}(x_n; \frac{1}{n})$ can't be covered finitely. Then $\overline{B}(x_n; 1/n) \downarrow B = \{a\}$ (Theorem 3.3) can't be finitely covered by any subcover of Ω , which means Ω can't cover the whole K , leading to the contradiction. \square

§4 Connected Set

Definition 4.1 (Connected space). Topological space (X, \mathcal{T}) is called **connected** if there is no **open-closed set** (i.e. both open and closed) besides \emptyset and X itself.

Notice that if $A \in 2^X$ is open-closed, its complement $X - A$ is also open-closed, which means a topological space is connected **iff** it is not a union of its two open subsets.

Definition 4.2 (Connected set). Let (X, \mathcal{T}) be a topological space. Subset C is said to be **connected** if subspace (C, \mathcal{T}_C) is connected.

Theorem 4.1. *Let (X, \mathcal{T}) be a topological space, and $\{C_\alpha\}_{\alpha \in A}$ be connected subsets of X . If $\bigcap_{\alpha \in A} C_\alpha \neq \emptyset$, then $\bigcup_{\alpha \in A} C_\alpha$ is also connected.*

Proof. Assume that $C = \bigcup_{\alpha \in A} C_\alpha$ were not connected, $\exists E \in 2^C$ s.t. $E \neq \emptyset$, $E \neq C$ and $E, C - E \in \mathcal{T}_C$. For E is not empty there exists a $\beta \in A$ s.t. $E \cap C_\beta \neq \emptyset$.

Now we show that $C_\beta \subset E$. Suppose that $C_\beta \not\subset E$, which implies that $(C - E) \cap C_\beta \neq \emptyset$. $E, C - E, C_\beta \in \mathcal{T}_C$, by the definition of the topology, $E \cap C_\beta, (C - E) \cap C_\beta \in \mathcal{T}_C$. This conflicts to the fact that C_β is connected. Therefore $C_\beta \subset E$.

Hence, there exists a $B \subsetneq A$, $\bigcup_{\beta \in B} C_\beta = A$. Since C_γ , $\gamma \in A - B$ would have a empty intersection with E , which contradicts $\bigcap_{\alpha \in A} C_\alpha \neq \emptyset$. \square

Theorem 4.2. *Connected sets have connected closure.*

Proof. \square

Theorem 4.3. $C \subset \mathbb{R}$ is connected iff $\forall x, z \in C \forall y \in \mathbb{R} (x < y < z) \rightarrow y \in C$.

Proof. \rightarrow : Assume that there were such $y \in \mathbb{R}$ that $\exists x, z \in C$, $x < y < z$ but $y \notin C$. $\{x \in C \mid x < y\}$ and $\{x \in C \mid x > y\}$ are open in C for they are intersection of open sets in \mathbb{R} and C . Since they're each other's complement, they are both open-closed, which conflicts to the definition of a connected set.

\leftarrow : It can be proved that $(\inf C, \sup C) \subset C$. Assume that there were an open-closed proper subset $E \neq \emptyset$ contained in C . Find two points $x \in E$, $z \in C - E$. Without loss of generality, let $x < z$. Since E and $C - E$ are closed, $c_1 = \inf (E \cap [a, b]) \in E$ while $c_2 = \inf ((C - E) \cap [a, b]) \in C - E$. However $E \cap (C - E) = \emptyset$, hence $c_1 < c_2$, which means $(c_1, c_2) \cap E = \emptyset$. Here's the contradiction. \square

Definition 4.3 (Locally connected). A topological space (X, \mathcal{T}) is said to be **locally connected** if $\forall x \in X$, $\exists U(x)$ s.t. $U(x)$ is connected.

§5 Complete Metric Spaces

We now take a closer look at one of the most important examples of metric spaces: complete spaces.

Definition 5.1 (Cauchy sequence). A sequence $(x_n)_{n \in \mathbb{N}}$ of points in a metric space (X, d) is called a **fundamental sequence** or **Cauchy sequence** if $\forall \varepsilon \in \mathbb{R}_+$, $\exists N \in \mathbb{N}$ s.t. as long as $m, n > N$, $d(x_n, x_m) < \varepsilon$.

Definition 5.2 (complete space). A metric space (X, d) is **complete** if any Cauchy sequence of its points is convergent.

For example, a metric space $C_\infty[a, b]$ is complete while $C_1[a, b]$ isn't. The proof see [1, p. 22].

Let us consider an incomplete space \mathbb{Q}_1 , which is a subspace of the complete space \mathbb{R}_1 . If \mathbb{R}_1 is the smallest complete space containing \mathbb{Q}_1 , we can say that we have achieved a **completion** of \mathbb{Q}_1 . However, the term "smallest" hasn't been properly defined yet.

Definition 5.3 (completion). If a metric space (X, d) is a subspace of a complete metric space (Y, d) and everywhere dense in it, we call the latter one the **completion** of (X, d) .

We need to confirm that such completion is the smallest and unique. So we introduce:

Definition 5.4 (isometry). If there exists a **isometry** $f: X_1 \rightarrow X_2$ when (X_1, d_1) and (X_2, d_2) are both metric space, i.e. f is a bijective and $\forall a, b \in X_1$, $d_2(f(a), f(b)) = d_1(a, b)$, then these two metric spaces are **isometric**.

This relation is reflexive (id_X), symmetric (f^{-1}), and transitive ($f \circ g$), so it is an equivalence relation, denoted by \sim . We shall consider isometric spaces as identical, when only discussing within metric topological topics.

Theorem 5.1. *If metric spaces (Y_1, d_1) and (Y_2, d_2) are both completions of (X, d) , then they are isometric.*

Proof. Between two completions such isometry $f: Y_1 \rightarrow Y_2$ can be defined: if $x_1, x_2 \in X$,

$$d_2(f(x_1), f(x_2)) = d(f(x_1), f(x_2)) = d(x_1, x_2) = d_1(x_1, x_2).$$

For each $y_1 \in Y_1 - X$, a Cauchy sequence $(x_n)_{n \in \mathbb{N}}$ can be found in the nested sequence of balls centered in y_1 . It is obvious that $(x_n)_{n \in \mathbb{N}}$ is also fundamental in Y_2 , limiting to $y_2 \in Y_2$.

Differently selected sequences of points $(x'_n)_{n \in \mathbb{N}}$ won't limit to a different y'_2 , namely $d(x_n, x'_n)$ shall converge to 0, or the fact that the radii of balls converge to 0 would be violated.

Let $f(y_1) = y_2$.

- a) For each $y_2 \in Y_2 - X$, there always exists a Cauchy sequence converging to it, which implies that f is a surjection.
- b) On the other hand, we shall notice that $\forall y'_1, y''_1 \in Y_1 - X$,

$$d_1(y'_1, y''_1) = \lim_{n \rightarrow \infty} d(x'_n, x''_n) = d_2(y'_2, y''_2)$$

while $(x'_n)_{n \in \mathbb{N}}$ and $(x''_n)_{n \in \mathbb{N}}$ are both Cauchy sequences. This equality proved that f is an injection. □

Theorem 5.2. *There always exists a completion for every metric space.*

Proof. Let $C_X := \{(x_n)_{n \in \mathbb{N}} \in X^{\mathbb{N}} \mid \forall \varepsilon \in \mathbb{R}_+, \exists N \in \mathbb{N} \text{ s.t. } \forall n, m \in \mathbb{N} (n > N \wedge m > N \rightarrow d_X(x_n, x_m) < \varepsilon)\}$, namely the collections of Cauchy sequences in X .

We say two Cauchy sequences $(x_n)_{n \in \mathbb{N}}$, $(x'_n)_{n \in \mathbb{N}}$ are equivalent (or, we shall say in a complete space, that they have a same limit) if $\lim_{n \rightarrow \infty} d(x_n, x'_n) = 0$.

It can be easily proved that such relation is an equivalence relation, and it divides C_X into equivalence classes S .

$\forall (x_n)_{n \in \mathbb{N}}, (x'_n)_{n \in \mathbb{N}} \in C_X, \forall \varepsilon \in \mathbb{R}_+, \exists N \in \mathbb{N} \text{ s.t. } \forall n, m \in \mathbb{N}, \text{ as long as } n > N \text{ and } m > N \text{ (by Lemma 1):}$

$$|d_X(x_n, x'_n) - d_X(x_m, x'_m)| \leq d_X(x_n, x_m) + d_X(x'_n, x'_m) < 2\varepsilon.$$

Hence, $(d(x_n, x'_n))_{n \in \mathbb{N}}$ is a Cauchy sequence in \mathbb{R}_1 . Since \mathbb{R}_1 is a complete space, $\lim_{n \rightarrow \infty} d(x_n, x'_n)$ always exists. This fact allows us to introduce⁴:

$$d: S^2 \rightarrow \mathbb{R}; ((x_n)_{n \in \mathbb{N}}), ((x'_n)_{n \in \mathbb{N}}) \mapsto \lim_{n \rightarrow \infty} d(x_n, x'_n)$$

A metric space (S_X, d) isometric to any given metric space (X, d_X) can be constructed, where $S_X := \{[(x_n)_{n \in \mathbb{N}}] \mid x \in X\}$.

Then we shall show that S is the completion of S_X .

⁴We implicitly use the (countable) axiom of choice: we must find a Cauchy sequence for each equivalence class.

Let $((x_n^i)_{n \in \mathbb{N}})_{i \in \mathbb{N}}$ be a Cauchy sequence in S . By definition, for any $i \in \mathbb{N}_+$, there exists a N that is large enough such that as long as $j > N$, $k > N$, $d_X(x_j^i, x_k^i) < 1/i$. Choose $a^i := x_k^i$ for such $k > N$, so that $d([(a^i)_{n \in \mathbb{N}}], [(x_n^i)_{n \in \mathbb{N}}]) < 1/i$.

$\forall \varepsilon \in \mathbb{R}_+$, $\exists N \in \mathbb{N}$ (e.g. we can choose $N = \lfloor 4/\varepsilon \rfloor$) s.t. $\forall n, m \in \mathbb{N}$, $p > N \wedge q > N \rightarrow$

$$d([(x_n^p)_{n \in \mathbb{N}}], [(x_n^q)_{n \in \mathbb{N}}]) < \frac{\varepsilon}{2} \wedge d([(x_n^p)_{n \in \mathbb{N}}], [(a^p)_{n \in \mathbb{N}}]) < \frac{1}{p} \wedge d([(x_n^q)_{n \in \mathbb{N}}], [(a^q)_{n \in \mathbb{N}}]) < \frac{1}{q},$$

therefore when p, q are great enough, (by the triangle inequality)

$$d([(a^p)_{n \in \mathbb{N}}], [(a^q)_{n \in \mathbb{N}}]) \leq \frac{\varepsilon}{2} + \frac{1}{p} + \frac{1}{q} < \varepsilon.$$

So, $[(a^n)_{n \in \mathbb{N}}]$ is a Cauchy sequence, therefore it is an element of S .

By $\lim_{i \rightarrow \infty} d([(x_n^i)_{n \in \mathbb{N}}], [(a^n)_{n \in \mathbb{N}}]) = 0$, we found a limit for the arbitrary Cauchy sequence $((x_n^i)_{n \in \mathbb{N}})_{i \in \mathbb{N}}$ in S .

Finally, we have to check that S_X is everywhere dense in S . For any arbitrary $[(x_n)_{n \in \mathbb{N}}] \in S$, $\forall \varepsilon$, we can always choose a $N \in \mathbb{N}$ great enough so that $[(x_N)_{n \in \mathbb{N}}] \in S_X \cap B([(x_n)_{n \in \mathbb{N}}], \varepsilon)$. Since every neighbourhood of $[(x_n)_{n \in \mathbb{N}}]$ contains a ball centred at it, we have proved that $\forall U \in \mathcal{U}([(x_n)_{n \in \mathbb{N}}]) (U \cap S_X \neq \emptyset)$. \square

Note: We have already seen such technique when we construct the real numbers from the sequences of rational numbers.

§6 Continuous Mapping

Let's recall the definition of the limitation.

Definition 6.1 (Filter base). A set $\mathcal{B} \subset 2^X$ is called a **(filter) base** in X if the following conditions hold:

- a) $\emptyset \notin \mathcal{B}$.
- b) $\forall B_1, B_2 \in \mathcal{B}$, $\exists B \in \mathcal{B}$ s.t. $B \subset B_1 \cap B_2 \subset B_2$.

Here is a list of some important filter bases:

- (1) $x \rightarrow a$, where $a \in X$, means $\mathcal{U}(a)$;
- (2) $x \rightarrow \infty$, means $\{V \mid X - V \in \mathcal{U}(a) - \{X\}\}$;
- (3) $E \ni x \rightarrow a$, means $\{\mathring{U}(a) \cap E \mid \mathring{U}(a) \in \mathcal{U}(a)\}$;
- (4) $E \ni x \rightarrow \infty$, means $\{E \cap V \mid X - V \in \mathcal{U}(a) - \{X\}\}$.

Introduction of the limits in a topological space is as follows.

Definition 6.2 (Limit). Let $a \in Y$ be the **limit** over the base $\mathcal{B} \subset 2^{\mathcal{D}(f)}$ of a mapping $f: \mathcal{D}(f) \rightarrow Y$, in which Y is equipped with a topology \mathcal{T} .

$$\lim_{\mathcal{B}} f = a \quad := \quad \forall U(a) \in \mathcal{U}(a) \exists B \in \mathcal{B} (f(B) \subset U(a)).$$

Such definition is parallel to the definition we have introduced on the limits of real number, hence it basically holds the same propoties, except for:

Theorem 6.1 (Uniqueness of limit in Hausdorff space). *Let Y be a Hausdorff space, \mathcal{B} be a filter base in X , $f \in Y^X$. The limit of f over \mathcal{B} is unique.*

Definition 6.3 (Oscillation). Let X, Y be two topological spaces, $f \in Y^X$, $E \in \mathcal{P}(X)$.

$$\omega(f; E) := \sup\{d_Y(f(x_1), f(x_2)) \mid x_1, x_2 \in E\}$$

is called the **oscillation** of the function f in set E . We can also define the **oscillation** of f at a point $x \in X$ as

$$\omega(f; x) := \inf\{\omega(f; B) \mid B \in \mathcal{B}\},$$

where \mathcal{B} is a filter base that $\cap \mathcal{B} = \{x\}$.

Theorem 6.2 (Cauchy criterion for existence of limit). *Let \mathcal{B} be a filter base in X , (Y, d) be a complete metric space, and $f \in Y^X$. The mapping f has a limit over base \mathcal{B} iff $\forall \varepsilon \in \mathbb{R}_+$, $\exists B \in \mathcal{B}$ s.t. $\omega(f; B) < \varepsilon$.*

Proof. \rightarrow : Denote $a := \lim_{\mathcal{B}} f$. $\forall \varepsilon$, $\exists B \in \mathcal{B}$ s.t. $f(B) \subseteq B(a; \varepsilon/2)$

$$\forall x, x' \in B, \quad d(f(x), f(x')) \leq d(f(x), a) + d(f(x'), a) < \varepsilon.$$

\leftarrow : $\forall n \in \mathbb{N}_+$, $\exists B_n \in \mathcal{B}$ s.t. $\omega(f; B_n) < 1/n$. Since $B_n \neq \emptyset$ (the definition of filter base), we can choose⁵ $x_n \in B_n$ for any n , so that we get a sequence $\langle f(x_n) \rangle_{n \in \mathbb{N}} \in Y^{\mathbb{N}}$. Let $x \in B_n \cap B_m$ for any m, n that $m > 1/\varepsilon$, $n > 1/2\varepsilon$ for any ε

$$d(f(x_n), f(x_m)) \leq d(f(x_n), f(x)) + d(f(x_m), f(x)) < \varepsilon,$$

hence $\langle f(x_n) \rangle_{n \in \mathbb{N}}$ is a Cauchy sequence, by the completeness of Y we can find a limit a for it.

Let $m \rightarrow \infty$ we get $d(f(x_n), a) \leq \varepsilon$. This inequality holds for any ε and n great enough. $\forall x' \in B_n$,

$$d(f(x'), a) \leq d(f(x'), f(x_n)) + d(f(x_n), a) < \frac{1}{n} + \varepsilon,$$

the right-hand side can be arbitrary small, if n is even greater. \square

Definition 6.4 (Continuity). A mapping $f: X \rightarrow Y$, where X, Y is equiped with topology $\mathcal{T}_X, \mathcal{T}_Y$, respectively, is said to be **continuous** at $x_0 \in X$ (let $y_0 = f(x_0) \in Y$), if $\forall U(y_0)$, $\exists U(x_0)$ s.t. $f(U(x_0)) \subset U(y_0)$. It is **continuous** in X if it is continuous at each point $x \in X$.

The set of continuous mappings from X into Y can be denoted by $C(X, Y)$ or $C(X)$ when Y is clear.

Theorem 6.3 (Criterion for continuity). *Let (X, \mathcal{T}_X) and (Y, \mathcal{T}_Y) be two topological spaces, $f \in Y^X$. The function f is continuous iff $\forall G_Y \in \mathcal{T}_Y$, $f^{-1}(G_Y) \in \mathcal{T}_X$.*

Proof. \rightarrow : It is obvious if $f^{-1}(G_Y) = \emptyset$. Hence we assume that $f^{-1}(G_Y) \neq \emptyset$. Let $x_0 \in X$. Since $f \in C(X, Y)$, for G_Y , $\exists U(x_0)$ s.t. $f(U(x_0)) \subset G_Y$. Also notice that $f(U(x_0)) \subset G_Y \Rightarrow U(x_0) \subset f^{-1}(G_Y)$, therefore $f^{-1}(G_Y)$ is open.

\leftarrow : $\forall x_0 \in X$, let $y_0 = f(x_0)$, $f^{-1}(U(y_0)) \in \mathcal{T}_X$. Notice that $x_0 \in f^{-1}(U(y_0))$, therefore $f \in C(X, Y)$. \square

⁵I don't know any proof that can avoid using axiom of choices

Definition 6.5 (Homeomorphism). Let (X, \mathcal{T}_X) and (Y, \mathcal{T}_Y) be two topological spaces. A bijective mapping $f: X \rightarrow Y$ is a **homeomorphism** if $f \in C(X, Y) \wedge f^{-1} \in C(Y, X)$.

Definition 6.6 (Homeomorphic spaces). Two topological spaces (X, \mathcal{T}_X) and (Y, \mathcal{T}_Y) are said to be **homeomorphic** if there exists a homeomorphism $f: X \rightarrow Y$.

Homeomorphic topological spaces are identical with respect to their topological properties since the theorem 6.3 has shown that their open sets correspond to each other.

Theorem 6.4 (Continuity of compositions of functions). Let X, Y, Z be three topological spaces, $E \in \mathcal{P}(X)$. $f \in C(E, Y)$, $g \in C(f(E), Z)$, then

$$g \circ f \in C(E, Z).$$

Theorem 6.5 (Continuous then locally bounded). Let (X, \mathcal{T}) be a topological space and (Y, d) be a metric space, $f \in Y^X$, $x \in X$. If f is continuous at x , then $\exists U(x) \in \mathcal{U}(x)$ s.t. $U(x)$ is bounded.

Theorem 6.6 (Continuous iff oscillation is zero). Let X be a topological space and Y be a metric space, $f \in Y^X$, $x \in X$. The function f is continuous at x iff $\omega(f; x) = 0$.

Then we shall introduce some global properties of continuous mappings.

Theorem 6.7 (Conservation of compactness). Let (X, \mathcal{T}_X) and (Y, \mathcal{T}_Y) be two topological spaces. Let $K \subset X$ be a compact set. If $f: X \rightarrow Y \in C(X, Y)$, then $f(K)$ is compact.

Proof. For each open cover $\Omega_Y = \{G_Y \in \mathcal{T}_Y\} \subset \mathcal{T}_Y$ over $f(K)$, $f^{-1}(G_Y) \in \mathcal{T}_X$ (Theorem 6.3). $f(K) \subset \cup \Omega_Y \Rightarrow K \subset f^{-1}(\cup \Omega_Y) = \cup \Omega_X$, where $\Omega_X = \{f^{-1}(G_Y) \mid G_Y \in \Omega_Y\}$ is an open cover over K . Since K is compact, $\exists \Omega'_X \subset \Omega_X$ ($|\Omega'_X| \in \mathbb{N}_+ \wedge K \subset \cup \Omega'_X$), $f(K) \subset f(\cup \Omega'_X)$. $f(G'_X) \in \Omega_Y$, hence $\Omega'_Y = \{f(G'_X) \mid G'_X \in \Omega'_X\}$ is a finite subcover over $f(K)$. \square

Theorem 6.8 (Weierstrass maximum-value theorem). Let K be a compact topological space, and $f \in C(K, \mathbb{R})$. $\exists x_m, x_M \in K$, s.t. $f(x_m) = m := \inf f(K)$, $f(x_M) = M := \sup f(K)$.

Proof. By Theorem 6.7, $f(K)$ is also compact, and therefore closed (Theorem 3.4). If $M \notin f(K)$, then open covers $\{B(M; (M - m)/n) - \tilde{B}(M; (M - m)/(n + 1)) \mid n \in \mathbb{N}_+\}$ would not have a finite subcover, which is a contradiction to the compactness of $f(K)$. \square

Theorem 6.9 (Bijective from compact space to Hausdorff space is homeomorphism). Let (K, \mathcal{T}_K) be a compact space and (Y, \mathcal{T}_Y) be a Hausdorff space. Let $f \in Y^K$ be a bijective. If $f \in C(K, Y)$, then f is a homeomorphism.

Proof. $\forall F = K - G$ s.t. $G \in \mathcal{T}_K$ is compact (Theorem 3.4). Hence $f(F)$ is compact (Theorem ??), then it is also closed (Theorem 3.2). This fact shows that f^{-1} is continuous (Theorem 6.3). \square

Definition 6.7 (Uniformly continuous). Let (X, d_X) , (Y, d_Y) be metric spaces, $f \in Y^X$. If $\forall \varepsilon \in \mathbb{R}_+$, $\exists \delta \in \mathbb{R}$, $\forall x \in X$ s.t. $\forall E \in \mathcal{P}(X)$,

$$d_X E < \delta \quad \rightarrow \quad \omega(f; E) < \varepsilon,$$

then f is said to be a **uniformly continuous** mapping.

Theorem 6.10 (Heine-Cantor theorem). *Let (K, d_K) be a compact metric space, and (Y, d_Y) be a metric space. $\forall f \in C(K, Y)$, f is uniformly continuous.*

Proof. $\forall \varepsilon \in \mathbb{R}_+$, we can find a collections of open balls

$$\Omega = \{B(x; \delta(x)/2) \mid x \in X, \omega(f; B(x; \delta(x))) < \varepsilon\},$$

that covers the compact set K , then there exists a finite subcover $\Omega' = \{B(x_i; \delta(x_i)/2)\}_{i \in n}$. Let $\delta := \min\{\delta(x_i)\}_{i \in n}$.

$$\forall x', x'' \in K, \exists i \in n, x' \in B(x_i; \delta(x_i)/2), \text{ if } d(x', x'') < \delta,$$

$$\delta(x'', x_i) \leq \delta(x', x'') + \delta(x', x'') < \delta + \delta(x_i) \leq \delta(x_i),$$

therefore $x', x'' \in B(x_i; \delta(x_i))$, we have assume that $\omega(f; B(x_i; \delta(x_i)))$. □

Theorem 6.11 (Conservation of connectedness). *Let (X, \mathcal{T}_X) and (Y, \mathcal{T}_Y) be two topological spaces, and $E \subset X$ be a connected set. If $f \in C(X, Y)$, then $f(E)$ is also connected.*

Proof. Only to notice that the open-closed sets in $(f(E), \mathcal{T}_{f(E)})$ have concurrently open-closed pre-images in (E, \mathcal{T}_E) . □

Theorem 6.12 (Intermediate-value theorem). *Let (X, \mathcal{T}) be a connected topological space, and $f \in C(X, \mathbb{R})$, $f(a) = A$, $f(b) = B$, $A < B$. $\forall C \in [A, B]$, $\exists c \in X$, $f(c) = C$.*

Proof. by Theorem 6.11, $f(X)$ must be a connected set. Hence by Theorem 4.3, we know that $\forall C \in [A, B]$, $C \in f(X)$. □

§7 Contraction

Definition 7.1 (Fixed point). A point $a \in X$ is a **fixed point** of a mapping $f: X \rightarrow X$ if $f(a) = a$.

Definition 7.2 (Contraction). Let (X, d) be a metric space. A mapping $f: X \rightarrow X$ is called a **contraction** if $\exists q \in (0, 1) \subset \mathbb{R}$ s.t. $\forall x_1, x_2 \in X$,

$$d(f(x_1), f(x_2)) \leq qd(x_1, x_2). \tag{7-1}$$

Lemma 4. *A contraction $f: X \rightarrow X$ is always continuous.*

Proof. $\forall x \in X$, $\forall \varepsilon \in \mathbb{R}_+$, $\exists \delta < \varepsilon/q$, according to inequality 7-1:

$$f(B(x; \delta)) \subset B(f(x); \varepsilon).$$

□

Theorem 7.1 (Picard-Banach fixed-point principle or contraction mapping principle). *Let (X, d) be a complete metric space. Each contraction $f: X \rightarrow X$ has a unique fixed point a . Also, $\forall \{x_n\} \subset X$ s.t. $\forall n \in \mathbb{N} (f(x_n) = x_{n+1})$ then $\lim_{n \rightarrow \infty} x_n = a$, and*

$$d(x_n, a) \leq \frac{q^n}{1 - q} d(x_1, x_0). \tag{7-2}$$

Proof. By the inequality 7-1:

$$d(x_{n+1}, x_n) \leq qd(x_n, x_{n-1}) \leq \cdots \leq q^n d(x_1, x_0)$$

Therefore, $\forall n, k \in \mathbb{N}$,

$$d(x_{n+k}, x_n) \leq \sum_{i=0}^{k-1} d(x_{n+i+1}, x_{n+i}) \leq \sum_{i=0}^{k-1} q^{n+i} d(x_1, x_0) \leq \frac{q^n}{1-q} d(x_1, x_0), \quad (7-3)$$

which implies that $\langle x_n \rangle_{n \in \mathbb{N}}$ is a Cauchy sequence in a complete space (X, d) , hence it converges to a point $a \in X$.

To proof that a is a fixed point of f , since f is continuous (Lemma 4), just notice that

$$a = \lim_{n \rightarrow \infty} f(x_n) = f(\lim_{n \rightarrow \infty} x_n) = f(a).$$

If there were another fixed point $a' \in X$ of f , then:

$$0 \leq d(a, a') = d(f(a), f(a')) \leq qd(a, a')$$

which can't be true unless $a = a'$.

By passing to the limit as $k \rightarrow \infty$ in the inequality 7-3, we have the inequality 7-2. □

Chapter 2

Normed Linear Space and Differential Calculus

§8 Normed Linear Space

Definition 8.1 (Norm). Let V be a linear space over \mathbb{R} or \mathbb{C} . A function $\|\cdot\|: X \rightarrow \mathbb{R}$ assigning to each vector $\mathbf{x} \in X$ a real number $\|\mathbf{x}\|$ is called a **norm** in the linear space X if:

- a) $\|\mathbf{x}\| = 0 \leftrightarrow \mathbf{x} = \mathbf{0}$ (nondegeneracy);
- b) $\|\lambda\mathbf{x}\| = |\lambda|\|\mathbf{x}\|$ (homogeneity);
- c) $\|\mathbf{x}_1 + \mathbf{x}_2\| \leq \|\mathbf{x}_1\| + \|\mathbf{x}_2\|$ (the triangle inequality).

A linear space with a norm defined on it is said to be **normed**.

Over every normed space a distance can be defined as:

$$d(\mathbf{x}_1, \mathbf{x}_2) = \|\mathbf{x}_1 - \mathbf{x}_2\| \quad (8-1)$$

Definition 8.2 (Banach space). Let V be a normed space. If (V, d) is a complete space, where the distance d is defined as Eq. (8-1), then we call V a **complete normed space** or **Banach space**.

Definition 8.3 (Hermitian form). A linear space X on the complex field \mathbb{C} is said to be given a **Hermitian space** if there is a mapping $\langle \cdot, \cdot \rangle: X^2 \rightarrow \mathbb{C}$ defined, s.t. $\forall \mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3 \in X, \forall \lambda \in \mathbb{C}$.

- a) $\langle \mathbf{x}_1, \mathbf{x}_2 \rangle = \overline{\langle \mathbf{x}_2, \mathbf{x}_1 \rangle}$;
- b) $\langle \lambda \mathbf{x}_1, \mathbf{x}_2 \rangle = \lambda \langle \mathbf{x}_1, \mathbf{x}_2 \rangle$;
- c) $\langle \mathbf{x}_1 + \mathbf{x}_2, \mathbf{x}_3 \rangle = \langle \mathbf{x}_1, \mathbf{x}_3 \rangle + \langle \mathbf{x}_2, \mathbf{x}_3 \rangle$.

A Hermitian form is said to be **positive semi-definite**, if $\forall \mathbf{x} \in X, \langle \mathbf{x}, \mathbf{x} \rangle \geq 0$ ¹. A Hermitian form is said to be **degenerate**, if $\exists \mathbf{x} \in X - \{\mathbf{0}\}$ s.t. $\langle \mathbf{x}, \mathbf{x} \rangle = 0$. A Hermitian form that is not degenerate is said to be **non-degenerate**.

¹ $\langle \mathbf{x}, \mathbf{x} \rangle = \overline{\langle \mathbf{x}, \mathbf{x} \rangle}$, hence $\langle \mathbf{x}, \mathbf{x} \rangle \in \mathbb{R}$.

Definition 8.4 (Inner product). A non-degenerate positive semi-definite Hermitian form² is said to be an **inner product**. A space equipped with an inner product is said to be a **inner product space**.

Theorem 8.1 (Cauchy-Bunyakovskii's inequality). A linear space X on the complex field \mathbb{C} is equipped with an inner product \langle, \rangle . $\forall \mathbf{x}, \mathbf{y} \in X$,

$$|\langle \mathbf{x}, \mathbf{y} \rangle|^2 \leq \langle \mathbf{x}, \mathbf{x} \rangle \langle \mathbf{y}, \mathbf{y} \rangle. \quad (8-2)$$

Proof. The theorem is trivial as $\mathbf{y} = \mathbf{0}$. Let us assume that $\mathbf{y} \neq \mathbf{0}$, therefore $\langle \mathbf{y}, \mathbf{y} \rangle > 0$.

$\forall \lambda \in \mathbb{C}$,

$$0 \leq \langle \mathbf{x} + \lambda \mathbf{y}, \mathbf{x} + \lambda \mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{x} \rangle + \lambda \overline{\langle \mathbf{x}, \mathbf{y} \rangle} + \bar{\lambda} \langle \mathbf{x}, \mathbf{y} \rangle + |\lambda|^2 \langle \mathbf{y}, \mathbf{y} \rangle$$

Let $\lambda = -\langle \mathbf{x}, \mathbf{y} \rangle / \langle \mathbf{y}, \mathbf{y} \rangle$, we have:

$$0 \leq \langle \mathbf{x}, \mathbf{x} \rangle - \frac{|\langle \mathbf{x}, \mathbf{y} \rangle|^2}{\langle \mathbf{y}, \mathbf{y} \rangle}.$$

□

By the theorem 8.1 we can claim that a linear space on complex number with an inner product \langle, \rangle induces a norm

$$\|\mathbf{x}\| := \sqrt{\langle \mathbf{x}, \mathbf{x} \rangle}, \quad (8-3)$$

and a metric

$$d(\mathbf{x}, \mathbf{y}) = \|\mathbf{x} - \mathbf{y}\|. \quad (8-4)$$

Definition 8.5 (Hilbert space). If a linear space is equipped with an inner product, and together with its induced metric constructs a complete metric space, we call it a **Hilbert space**. If the induced metric space is not complete, we shall call it a **pre-Hilbert space**.

§9 Linear Operators

Definition 9.1 (Norm). Let \mathcal{A} be a n -multilinear operator space over normed space $(\mathbf{X}_i)_{i \in n}$ to a normed space Y i.e. $\mathcal{A} \in \mathcal{L}(X_0, X_1, \dots, X_{n-1}; Y)$. We define the norm $\|\mathcal{A}\|$ as:

$$\|\mathcal{A}\| := \sup \left\{ \frac{\|\mathcal{A}(\mathbf{x}_i)_{i \in n}\|_Y}{\prod_{i \in n} \|\mathbf{x}_i\|_{X_i}} \mid \forall i \in n, \mathbf{x}_i \in X_i - \{\mathbf{0}\} \right\}, \quad (9-1)$$

where the subscripts denote which spaces the norms are defined in.

The following theorem gives an equivalent definition:

Theorem 9.1. Let $\mathcal{A} \in \mathcal{L}(X_0, X_1, \dots, X_{n-1}; Y)$.

$$\|\mathcal{A}\| = \{\|\mathcal{A}(\mathbf{e}_i)_{i \in n}\|_Y \mid \forall i \in n, \mathbf{e}_i \in X_i \wedge \|\mathbf{e}_i\|_{X_i} = 1\}. \quad (9-2)$$

²Equivalently, a positive definite Hermitian form.

Theorem 9.2. Let $\mathcal{A} \in \mathcal{L}(X_0, X_1, \dots, X_{n-1}; Y)$, and let $\|\mathcal{A}\| < \infty$.

$$\|\mathcal{A}(\mathbf{x})_{i \in n}\|_Y \leq \|\mathcal{A}\| \prod_{i \in n} \|\mathbf{x}_i\|_{X_i}. \quad (9-3)$$

Definition 9.2 (Bounded linear operators). Let $\mathcal{A} \in \mathcal{L}(X_0, X_1, \dots, X_{n-1}; Y)$. If $\|\mathcal{A}\| < \infty$, then \mathcal{A} is said to be **bounded**.

Theorem 9.3 (Continuous at zero iff bounded). Let $\mathcal{A} \in \mathcal{L}(X_0, X_1, \dots, X_{n-1}; Y)$. Denote $\prod_{i \in n} X_i$ by X . The operator \mathcal{A} is continuous at $\mathbf{0} \in X$ ³ iff it is bounded.

Proof. First assume that \mathcal{A} is bounded.

When $\|\mathcal{A}\| = 0$ it is trivial. Hence we assume that $\|\mathcal{A}\| > 0$.

$\forall \varepsilon \in \mathbb{R}_+$, if $\Delta \mathbf{x} := (\Delta \mathbf{x}_i)_{i \in n} \in X$ meets the condition that $\forall i \in n, \|\Delta \mathbf{x}_i\|_{X_i} < \sqrt[n]{\varepsilon / \|\mathcal{A}\|}$ then

$$\begin{aligned} d_Y(\mathcal{A}(\mathbf{0} + \Delta \mathbf{x}), \mathcal{A}(\mathbf{0})) &= d_Y(\mathcal{A}(\Delta \mathbf{x}), \mathbf{0}) = \|\mathcal{A}(\Delta \mathbf{x})\|_Y \\ &\leq \|\mathcal{A}\| \prod_{i \in n} \|\Delta \mathbf{x}_i\|_{X_i} < \varepsilon. \end{aligned}$$

Then we assume that \mathcal{A} is continuous at $\mathbf{0}$.

Set any positive $\varepsilon \in \mathbb{R}_+$, $\exists \delta \in \mathbb{R}_+$, when $\forall i \in n, \mathbf{x}_i \in X_i - \{\mathbf{0}\}$ and $\|\mathbf{x}_i\|_{X_i} \leq \delta$, $\|\mathcal{A}(\mathbf{x})\| \leq \varepsilon$.

Since every unit vector \mathbf{e}_i can be written as $\delta \mathbf{e}_i / \delta$, where $\delta \mathbf{e}_i \in X_i - \{\mathbf{0}\}$ and $\|\delta \mathbf{e}_i\|_{X_i} = \delta$, then

$$\|\mathcal{A}(\mathbf{e}_i)_{i \in n}\|_Y = \frac{1}{\delta^n} \|\mathcal{A}(\delta \mathbf{e}_i)_{i \in n}\|_Y \leq \frac{\varepsilon}{\delta^n},$$

which implies that the operator \mathcal{A} is bounded. \square

Theorem 9.4 (Continuous at zero then at everywhere). Let $\mathcal{A} \in \mathcal{L}(X_0, X_1, \dots, X_{n-1}; Y)$. Denote $\prod_{i \in n} X_i$ by X . If the operator is continuous at $\mathbf{0} \in X$, then it is continuous in X .

Proof. By theorem 9.3, we have learned that an operator continuous at $\mathbf{0}$ is bounded.

$\forall \mathbf{x}, \Delta \mathbf{x} \in X$,

$$\begin{aligned} d_Y(\mathcal{A}(\mathbf{x} + \Delta \mathbf{x}), \mathcal{A}(\mathbf{x})) &= \|\mathcal{A}(\mathbf{x} + \Delta \mathbf{x}) - \mathcal{A}(\mathbf{x})\|_Y \\ &= \left\| \mathcal{A}(\Delta \mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \mathcal{A}(\mathbf{x}_1, \Delta \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \mathbf{x}_1, \dots, \Delta \mathbf{x}_{n-1}) \right. \\ &\quad \left. + \mathcal{A}(\Delta \mathbf{x}_0, \Delta \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \dots, \Delta \mathbf{x}_{n-2}, \Delta \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\Delta \mathbf{x}) \right\|_Y \\ &\leq \|\mathcal{A}(\Delta \mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{n-1})\|_Y + \dots + \|\mathcal{A}(\mathbf{x}_0, \mathbf{x}_1, \dots, \Delta \mathbf{x}_{n-1})\|_Y \\ &\quad + \dots + \|\mathcal{A}(\Delta \mathbf{x})\|_Y \\ &\leq \|\mathcal{A}\| \sum_{S \in \mathcal{P}(n) - \{\emptyset\}} \prod_{i \in n-S} \|\mathbf{x}_i\|_{X_i} \prod_{j \in S} \|\Delta \mathbf{x}_j\|_{X_j}. \end{aligned}$$

By setting $\max\{\|\mathbf{x}_i\|_{X_i} \mid i \in n\} < \varepsilon \max\left\{\sqrt[n]{\prod_{i \in n-S} \|\mathbf{x}_i\|_{X_i}} \mid S \in \mathcal{P}(n) - \{\emptyset\}\right\} / (2^n - 1) \|\mathcal{A}\|$ we have $d_Y(\mathcal{A}(\mathbf{x} + \Delta \mathbf{x}), \mathcal{A}(\mathbf{x})) < \varepsilon$ for any $\varepsilon \in \mathbb{R}_+$. \square

³Be reminiscent of the Definition 2.10

Theorem 9.3 and Theorem 9.4 show the equivalence for linear operators of being bounded and being continuous. We shall denote the space of all the bounded n -multilinear operators from X_0, \dots, X_{n-1} to Y by $\mathcal{B}(X_0, \dots, X_{n-1}; Y)$.

Corollary 1 (Linear operators from finite dimensional space are continuous). *If $\forall i \in n$, $\dim X_i < \infty$, then*

$$\mathcal{L}(X_0, \dots, X_{n-1}; Y) = \mathcal{B}(X_0, \dots, X_{n-1}; Y).$$

Corollary 2 (Continuous at a point then at everywhere). *Let $\mathcal{A} \in \mathcal{L}(X_0, X_1, \dots, X_{n-1}; Y)$. Denote $\prod_{i \in n} X_i$ by X , and Let $\mathbf{x} = (\mathbf{x}_i)_{i \in n} \in X$. If the operator is continuous at \mathbf{x} , then it is continuous in X .*

Proof. □

Definition 9.3 (Isomorphism). Two normed space are **isomorphic** if their exists an **isomorphism** f between them, s.t. f is a isomorphism between two linear space, and f and f^{-1} are continuous.

Theorem 9.5. *If two normed spaces have the same finite dimension, they are isomorphic.*

Theorem 9.6 (Space of bounded linear operators is normed linear space). $\mathcal{B}(X_0, \dots, X_{n-1}; Y)$ is a normed linear space, the norm is defined as in Eq. (9-1).

Theorem 9.7 (Norm of operator composition). *Let X, Y, Z be three normed spaces, and $\mathcal{A} \in \mathcal{B}(X; Y)$, $\mathcal{B} \in \mathcal{B}(Y; Z)$.*

$$\|\mathcal{B}\mathcal{A}\| \leq \|\mathcal{B}\| \|\mathcal{A}\|.^4$$

Proof.

$$\begin{aligned} \|\mathcal{B}\mathcal{A}\| &= \sup \{ \|\mathcal{B}\mathcal{A}\mathbf{x}\|_Z / \|\mathbf{x}\|_X \mid \mathbf{x} \in X - \{\mathbf{0}\} \} \\ &\leq \|\mathcal{B}\| \sup \{ \|\mathcal{A}\mathbf{x}\|_Y / \|\mathbf{x}\|_X \mid \mathbf{x} \in X - \{\mathbf{0}\} \} = \|\mathcal{B}\| \|\mathcal{A}\|. \end{aligned}$$

□

Theorem 9.8 (completeness). *If Y is a Banach space, so is $\mathcal{B}(X_0, \dots, X_{n-1}; Y)$.*

Proof. Let $(\mathcal{A}_i)_{i \in \mathbb{N}} \in \mathcal{B}(X_0, \dots, X_{n-1}; Y)^{\mathbb{N}}$ be a Cauchy sequence. $\forall \mathbf{x} := (\mathbf{x}_i)_{i \in n} \in X := \prod_{i \in n} X_i$,

$$\|\mathcal{A}_\ell \mathbf{x} - \mathcal{A}_m \mathbf{x}\|_Y = \|(\mathcal{A}_\ell - \mathcal{A}_m) \mathbf{x}\|_Y \leq \|\mathcal{A}_\ell - \mathcal{A}_m\| \prod_{i \in n} \|\mathbf{x}_i\|_{X_i},$$

therefore $(\mathcal{A}_i \mathbf{x})_{i \in \mathbb{N}} \in Y^{\mathbb{N}}$ is also a Cauchy sequence.

Since Y is a Banach space, we denote the limit of the Cauchy sequence $(\mathcal{A}_i \mathbf{x})_{i \in \mathbb{N}}$ by $\mathcal{A} \mathbf{x}$. We need to prove that $\mathcal{A} \in \mathcal{B}(X_0, \dots, X_{n-1}; Y)$.

It is obvious that $\mathcal{A} \in \mathcal{L}(X_0, \dots, X_{n-1}; Y)$, therefore we only need to show that $\|\mathcal{A}\| < \infty$.

Let $\mathbf{e} := (\mathbf{e}_i)_{i \in n} \in X$, where $\forall i \in n$, $\|\mathbf{e}_i\|_{X_i} = 1$. $\forall \varepsilon \in \mathbb{R}_+$, $\exists N \in \mathbb{N}$, if $\ell > N$, then

$$0 \leq \|\mathcal{A} \mathbf{e}\|_Y \leq \|\mathcal{A}_\ell \mathbf{e}\|_Y + \varepsilon \leq \|\mathcal{A}_\ell\| + \varepsilon,$$

Since $\{\|\mathcal{A}_i\| \mid i \in \mathbb{N}\}$ is bounded, we claim that $\{\|\mathcal{A} \mathbf{e}\| \mid \mathbf{e} = (\mathbf{e}_i)_{i \in n} \in X \wedge \forall i \in n (\|\mathbf{e}_i\|_{X_i} = 1)\}$ is also bounded. □

⁴By convention, we denote $\mathcal{B} \circ \mathcal{A}$ by $\mathcal{B}\mathcal{A}$, and $(\mathcal{B}\mathcal{A})(\mathbf{x})$ by $\mathcal{B}\mathcal{A}\mathbf{x}$ (since the compositions of the operator is associative).

Theorem 9.9. $\forall m \in n$,

$$\exists f \in \mathcal{B}(X_0, \dots, X_{n-1}; Y)^{\mathcal{B}(X_0, \dots, X_{m-1}; B(X_m, \dots, X_{n-1}; Y))}$$

s.t. f is a isomorphism between two linear spaces and it conserves the norm structure i.e.

$$\|f(\mathcal{B})\| = \|\mathcal{B}\|.$$

Proof. $\forall \mathcal{B} \in \mathcal{B}(X_0, \dots, X_{m-1}; B(X_m, \dots, X_{n-1}; Y))$, $\forall \mathbf{x} := (\mathbf{x}_i)_{i \in n} \in X := \prod_{i \in n} X_i$, $f(\mathcal{B})\mathbf{x} := \mathcal{B}(\mathbf{x}_i)_{i \in n}(\mathbf{x}_j)_{j \in n \setminus m}$.

Obviously $f \in \mathcal{L}(\mathcal{B}(X_0, \dots, X_{m-1}; B(X_m, \dots, X_{n-1}; Y)); \mathcal{B}(X_0, \dots, X_{n-1}; Y))$. If $f(\mathcal{B}) = \mathcal{O}_X$, $\mathcal{B} = \mathcal{O}_{\prod_{i \in m} X_m}$, therefore $\ker f = \{\mathcal{O}_{\prod_{i \in m} X_m}\}$, which implies that f is a isomorphism between two linear spaces.

$$\begin{aligned} \|\mathcal{B}\| &= \sup \left\{ \frac{\|\mathcal{B}(\mathbf{x}_i)_{i \in m}\|}{\prod_{i \in m} \|\mathbf{x}_i\|_{X_i}} \mid \forall i \in m, \mathbf{x}_i \in X_i \wedge \mathbf{x}_i \neq \mathbf{0} \right\} \\ &= \sup \left\{ \frac{\sup \left\{ \frac{\|f(\mathcal{B})(\mathbf{x})\|_Y}{\prod_{i \in n \setminus m} \|\mathbf{x}_i\|_{X_i}} \mid \forall i \in n \setminus m, \mathbf{x}_i \in X_i \wedge \mathbf{x}_i \neq \mathbf{0} \right\}}{\prod_{i \in m} \|\mathbf{x}_i\|_{X_i}} \mid \forall i \in m, \mathbf{x}_i \in X_i \wedge \mathbf{x}_i \neq \mathbf{0} \right\} \\ &= \sup \left\{ \frac{\|f(\mathcal{B})(\mathbf{x})\|_Y}{\prod_{i \in n} \|\mathbf{x}_i\|_{X_i}} \mid \forall i \in n, \mathbf{x}_i \in X_i \wedge \mathbf{x}_i \neq \mathbf{0} \right\} = \|f(\mathcal{B})\| \end{aligned}$$

□

Corollary 3. $\mathcal{B}(X_0; \mathcal{B}(X_1; \dots; \mathcal{B}(X_{n-1}; Y) \dots))$ and $\mathcal{B}(X_0, \dots, X_{n-1}; Y)$ are isomorphic.

§10 Differentiation

Definition 10.1 (Differentiation). Let X, Y be two normed spaces. A mapping f from $D \in \mathcal{P}(X)$ to Y is said to be **differentiable** at an interior point $\mathbf{x} \in D$ if $\exists \mathcal{L}(\mathbf{x}) \in \mathcal{B}(X; Y)$ ⁵ s.t. $\forall \Delta \mathbf{x} \in X$ ($\mathbf{x} + \Delta \mathbf{x} \in D$),

$$f(\mathbf{x} + \Delta \mathbf{x}) - f(\mathbf{x}) = \mathcal{L}(\mathbf{x})\Delta \mathbf{x} + \alpha(\mathbf{x}; \Delta \mathbf{x}), \quad (10-1)$$

where $\alpha(\mathbf{x}; \Delta \mathbf{x}) = o(\Delta \mathbf{x})$ as $\Delta \mathbf{x} \rightarrow 0$, i.e. $\lim_{\Delta \mathbf{x} \rightarrow 0} \|\alpha(\mathbf{x}; \Delta \mathbf{x})\|_Y / \|\Delta \mathbf{x}\|_X = 0$.

Such $\mathcal{L}|_{\mathbf{x}}$ is called the **differential** of f at \mathbf{x} ⁶, denoted by $\mathrm{d}f(\mathbf{x})$ or $f'(\mathbf{x})$.

Theorem 10.1 (Uniqueness). Let X and Y be two normed spaces. If a mapping $f \in Y^D$ where $D \in \mathcal{P}(X)$ is differentiable at \mathbf{x} which is an interior point of D , then the differential of f at \mathbf{x} is unique.

Proof. Let their be two differentials $\mathcal{L}_1(\mathbf{x})$, $\mathcal{L}_2(\mathbf{x})$, by the definition (10-1), we have:

$$(\mathcal{L}_1(\mathbf{x}) - \mathcal{L}_2(\mathbf{x}))\Delta \mathbf{x} = o(\Delta \mathbf{x}),$$

⁵ \mathbf{x} here is an argument.

⁶Alternatively, **tangent mapping** or **derivative**.

hence $\|(\mathcal{L}_1(\mathbf{x}) - \mathcal{L}_2(\mathbf{x}))\Delta\mathbf{x}\|_Y = o(\|\Delta\mathbf{x}\|_X)$, therefore

$$\lim_{\|\Delta\mathbf{x}\|_X \rightarrow 0} \left\| (\mathcal{L}_1(\mathbf{x}) - \mathcal{L}_2(\mathbf{x})) \frac{\Delta\mathbf{x}}{\|\Delta\mathbf{x}\|_X} \right\|_Y = 0,$$

This means that whatever the direction of unit vector $\Delta\mathbf{x}/\|\Delta\mathbf{x}\|_X$ is, the norm of $\|(\mathcal{L}_1(\mathbf{x}) - \mathcal{L}_2(\mathbf{x}))\Delta\mathbf{x}/\|\Delta\mathbf{x}\|_X\|_Y$ is always zero, therefore $\|\mathcal{L}_1(\mathbf{x}) - \mathcal{L}_2(\mathbf{x})\| = 0$. By the definition of norms, this means that $\mathcal{L}_1(\mathbf{x}) - \mathcal{L}_2(\mathbf{x}) = \mathcal{O}$, or $\mathcal{L}_1(\mathbf{x}) = \mathcal{L}_2(\mathbf{x})$. \square

Theorem 10.1 gives us the right to define:

Definition 10.2 (Derivative mapping). Let X, Y be two normed spaces, $D \in \mathcal{P}(X)$, $f \in Y^D$, $\Delta(f) := \{\mathbf{x} \in X \mid f \text{ is differentiable at } \mathbf{x}\}$.

$$f' : \Delta(f) \rightarrow \mathcal{B}(X, Y); \mathbf{x} \mapsto df(\mathbf{x})$$

is called the *derivative mapping* of f .

Warning: We use $f'(\mathbf{x})$ to denote the linear operator on X instead of a point in Y (when $X = Y = \mathbb{R}$, they are the isomorphic). It is obvious that $\forall \mathcal{A} \in \mathcal{B}(X; Y)$, $\forall \mathbf{x} \in X$, $d\mathcal{A}(\mathbf{x}) = \mathcal{A}$, which is different from the usual notations that writes $f(x) = e^x \rightarrow f'(x) = e^x = f(x)$ and $f(x) = ax \rightarrow f'(x) = a$.

To make it clear, we must remember: $f \in Y^X$, $f' \in \mathcal{B}(X; Y)^X$, $f'(\mathbf{x}) \in \mathcal{B}(X; Y)$, $f'(\mathbf{x})\Delta\mathbf{x} \in Y$.

It is always convenient to define such notation:

Definition 10.3. Let $X_i, i \in n$ be normed spaces, and $X := \prod_{i \in n} X_i$. We define $d\mathbf{x}_i$ as:

$$d\mathbf{x}_i \Delta\mathbf{x} = \Delta\mathbf{x}_i,$$

for any $\Delta\mathbf{x} := (\Delta\mathbf{x}_i)_{i \in n} \in X$.

Actually, $d\mathbf{x}_i$ can be conceive as the differential of the projective operator $X \rightarrow X_i$. If $n = 1$, $d\mathbf{x} = \text{id}_X$, therefore we can write:

$$df(\mathbf{x}) = f'(\mathbf{x}) d\mathbf{x},$$

which is the notation we have been very familiar with.

Theorem 10.2 (Differentiable then continuous). *Let X and Y be two normed spaces. If a mapping $f \in Y^D$ where $D \in \mathcal{P}(X)$ is differentiable at \mathbf{x} which is an interior point of D , then f is continuous at \mathbf{x} .*

Proof. as $\|\Delta\mathbf{x}\| \rightarrow 0$

$$\|f(\mathbf{x} + \Delta\mathbf{x}) - f(\mathbf{x})\|_Y \leq \|\mathcal{L}(\mathbf{x})\Delta\mathbf{x}\|_Y + \|\alpha(\mathbf{x}; \Delta\mathbf{x})\|_Y \leq \|\mathcal{L}(\mathbf{x})\| \|\Delta\mathbf{x}\|_X + \|\alpha(\mathbf{x}; \Delta\mathbf{x})\|_Y \rightarrow 0.$$

\square

We can denote all differentiable functions on X to Y by $C^{(1)}(X, Y)$ ⁷. By Theorem 10.2 we know that $C^{(1)}(X, Y) \subset C(X, Y)$.

⁷or $C^{(1)}(X)$ if you are sure about what Y is.

Theorem 10.3 (Linearity of differentiation). *Let X, Y be two normed space on \mathbb{F} (\mathbb{C} or \mathbb{R}), $C^{(1)}(X, Y)$ is also a linear space on \mathbb{F} .*

Theorem 10.4 (Chain rule). *Let X, Y, Z be three normed spaces, $D \in \mathcal{P}(X)$, $f \in Y^D$, $g \in Z^{f(D)}$, and f be differentiable at $\mathbf{x} \in D$, g be differentiable at $\mathbf{y} := f(\mathbf{x}) \in f(D)$.*

$$(g \circ f)'(\mathbf{x}) = g'(\mathbf{y})f'(\mathbf{x})^8.$$

For example, $(\mathcal{A} \circ f)'(\mathbf{x}) = \mathcal{A} \circ f'(\mathbf{x})$, since $\mathcal{A}'(\mathbf{y}) = \mathcal{A}$.

Theorem 10.5 (Differentiation of inverse mappings). *Let X, Y be two normed spaces, $D \in \mathcal{P}(X)$, bijective $f \in X^D$, and f be differentiable at $\mathbf{x} \in D$, and there be an inverse $[f'(\mathbf{x})]^{-1}$ for $f'(\mathbf{x})$. Then, f^{-1} is also differentiable at $\mathbf{y} := f(\mathbf{x})$, and*

$$(f^{-1})'(\mathbf{y}) = [f'(\mathbf{x})]^{-1}.$$

Consider a mappings $f: X \rightarrow Y$, where $Y := \prod_{i \in n} Y_i$, normed with $\|\mathbf{y}\|_Y := \sqrt[p]{\sum_{i \in n} \|\mathbf{y}_i\|_{Y_i}^p}$.

By writing f as $(f_i)_{i \in n}$ such that $f(\mathbf{x}) = (f_i(\mathbf{x}))_{i \in n}$, and

$$f'(\mathbf{x})\Delta\mathbf{x} = (f'_i(\mathbf{x})\Delta\mathbf{x})_{i \in n},$$

we can conclude that f is differentiable at $\mathbf{x} \in X$ **iff** for each $f_i: X \rightarrow Y_i$, $i \in n$, is differentiable at \mathbf{x} .

Theorem 10.6 (Differentiation of multilinear operators). *Let X_0, \dots, X_{n-1}, Y be normed spaces, $\mathcal{A} \in \mathcal{B}(X_0, \dots, X_{n-1}; Y)$. Let $X := \prod_{i \in n} X_i$ be normed space with a norm defined as:*

$$\forall \mathbf{x} := (\mathbf{x}_i)_{i \in n} \in X, \quad \|\mathbf{x}\|_X := \left(\sum_{i \in n} \|\mathbf{x}_i\|_{X_i}^p \right)^{1/p}. \quad (10-2)$$

Then,

$$\mathcal{A} \in C^{(1)}(X; Y), \quad d\mathcal{A}(\mathbf{x}) = \mathcal{A}(d\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \dots, \mathbf{x}_{n-2}, d\mathbf{x}_{n-1}).$$

Proof. By Eq. (10-2), we have $\forall i \in n$,

$$\|\mathbf{x}_i\|_{X_i} \leq \|\mathbf{x}\|_X \leq \sum_{j \in n} \|\mathbf{x}_j\|_{X_j}.$$

Therefore $\forall i, j \in n$,

$$\frac{\|\Delta\mathbf{x}_i\|_{X_i} \|\Delta\mathbf{x}_j\|_{X_j}}{\|\Delta\mathbf{x}\|_X} \leq \frac{\|\Delta\mathbf{x}_i\|_{X_i} \|\Delta\mathbf{x}_j\|_{X_j}}{\|\Delta\mathbf{x}_i\|_{X_i}} = \|\Delta\mathbf{x}_j\|_{X_j} \leq \|\Delta\mathbf{x}\|_X,$$

or $\|\Delta\mathbf{x}_i\|_{X_i} \|\Delta\mathbf{x}_j\|_{X_j} = o(\mathbf{x}; \Delta\mathbf{x})$.

$$\begin{aligned} \mathcal{A}(\mathbf{x} + \Delta\mathbf{x}) - \mathcal{A}(\mathbf{x}) &= \mathcal{A}(\Delta\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \mathcal{A}(\mathbf{x}_1, \Delta\mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \mathbf{x}_1, \dots, \Delta\mathbf{x}_{n-1}) \\ &\quad + \mathcal{A}(\Delta\mathbf{x}_0, \Delta\mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \dots, \Delta\mathbf{x}_{n-2}, \Delta\mathbf{x}_{n-1}) + \dots + \mathcal{A}(\Delta\mathbf{x}) \\ &= \mathcal{A}(\Delta\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \dots, \mathbf{x}_{n-2}, \Delta\mathbf{x}_{n-1}) + o(\mathbf{x}; \Delta\mathbf{x}), \end{aligned}$$

⁸Remember, we write the composition of two linear operators omitting the “o” in the middle.

where we utilize the fact that

$$\|\mathcal{A}(\Delta \mathbf{x}_0, \Delta \mathbf{x}_1, \dots, \mathbf{x}_{n-1})\|_Y \leq \|\mathcal{A}\| \|\Delta \mathbf{x}_0\|_{X_0} \|\Delta \mathbf{x}_1\|_{X_1} \prod_{i \in n \setminus 2} \|\mathbf{x}_i\|_{X_i} = o(\mathbf{x}; \Delta \mathbf{x}), \dots$$

Therefore

$$d\mathcal{A}(\mathbf{x})\Delta \mathbf{x} = \mathcal{A}(\Delta \mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \dots, \mathbf{x}_{n-2}, \Delta \mathbf{x}_{n-1})$$

or

$$d\mathcal{A}(\mathbf{x}) = \mathcal{A}(d\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{n-1}) + \dots + \mathcal{A}(\mathbf{x}_0, \dots, \mathbf{x}_{n-2}, d\mathbf{x}_{n-1}).$$
